Fixed multiplier also changes the step in the actual cell input
A. Fixed cell multiplier: raw residual declines
Residual energy x 1e6
Scale
m=0.5
m=1.3333
m=2
B. Per-step response does not decline uniformly
Residual energy / h squared x 1e6
C. Cell doubled: response and net error differ
Normalized response x 1e6
Total output change / h squared
Non-scalar energy / h squared
Net remainder H / h squared
D. Scale 2 to 6: symmetric endpoint accounting
Residual-energy decrease x 1e6
Step squared factor
Normalized response factor
h = 2(m-1)/s per axis. Finite-difference normalization is not a matched-step experiment or a Jacobian estimate.
